

Einführung in C - Introduction to C

7. Pointers and memory management

Prof. Dr. Eckhard Kruse

DHBW Mannheim

Variables and memory

A Variable is a place in computer memory, where values can be stored.

- The size of required memory depends on the type.
- How and where the memory is reserved is not directly controlled by the programmer.
 - Local variables: memory is reserved when the scope is entered and freed when it is left
 - Static/global variables: memory is reserved throughout the program's lifetime.

```
int a;           // reserves 4 bytes of memory
a=10;           // write 10 into the 4 bytes

char c='A';      // 1 byte
short li[3]={ 17, 5, 2 }; // 3*2 Bytes
```

Sizeof and &

Definition

The **sizeof** operator determines the size (in bytes) a data type or variable is using in memory.

```
short s;  
int array[4];  
  
printf("%d", sizeof(short));  
printf("%d", sizeof(s));  
printf("%d", sizeof(array));  
printf("%d", sizeof(array[0]));  
printf("%d", sizeof("Hallo"));
```

compile-time
vs. run-time
evaluation...

The **address operator &** provides the address, where a variable is stored in memory.

```
printf("%d", &s);  
printf("%p", &s); // pointer format: hex  
printf("%d", &array[0]);  
printf("%d", array); // same as &array[0]  
printf("%d", &"Test");
```

234548		
234547		
234546		
234545	2	li[2]
234544		
234543	5	li[1]
234542		
234541	17	li[0]
234540		

sizeof(li)
→ 6
&li[0]
→ 234540
